

# Lecture 22

## Code Generation for Procedures in WLP4

*CS 241: Foundations of Sequential Programs*  
Fall 2014

Troy Vasiga et al  
University of Waterloo

## A picture

Imagine we have code like:

```
int f(...) {...}  
int g(...) {...}  
int wain(...) {...}
```

What does it look like, in terms of RAM?

```
int f()  
int g()  
int wain()
```

wain:

```
<prologue>  
;  
;  
<epilogue>  
jr $3
```

2

f:

```
jr $3
```

g:

```
jr $3
```

## What does each procedure need to do?

Each procedure will have its own prologue and epilogue.

What should these contain?

- ▶ we don't need to worry about .import or .export ] → do this once, just in main
- ▶ we do need to worry about \$29 ]
- ▶ we do need to save registers
- ▶ we do need to restore registers
- ▶ we do need to return to our caller (i.e., jr \$31) ↗ each procedure has its own frame

## Saving registers

Overall (naive) idea: save "everything" \$1, \$2, \$5, \$6, \$29, \$31  
maybe

Suppose f calls g. Two approaches:

- ▶ Caller-save: f saves all registers which have useful information before calling g.
- ▶ Callee-save: g saves any register it is about to overwrite.

What have we been doing so far? Both.

hybrid → [ caller save: \$31  
                  callee save: everything else ]  
4

## What about \$29?

Suppose g (the callee) saves \$29.

messy {  
g must save registers on the stack and  
point \$29 to the bottom of g's frame  
change \$30: then need to calculate the bottom  
stack and make \$29 point there

Suppose f (the caller) saves \$29.

clean { g sets \$29  $\Rightarrow$  i.e. sub \$29, \$30, \$4

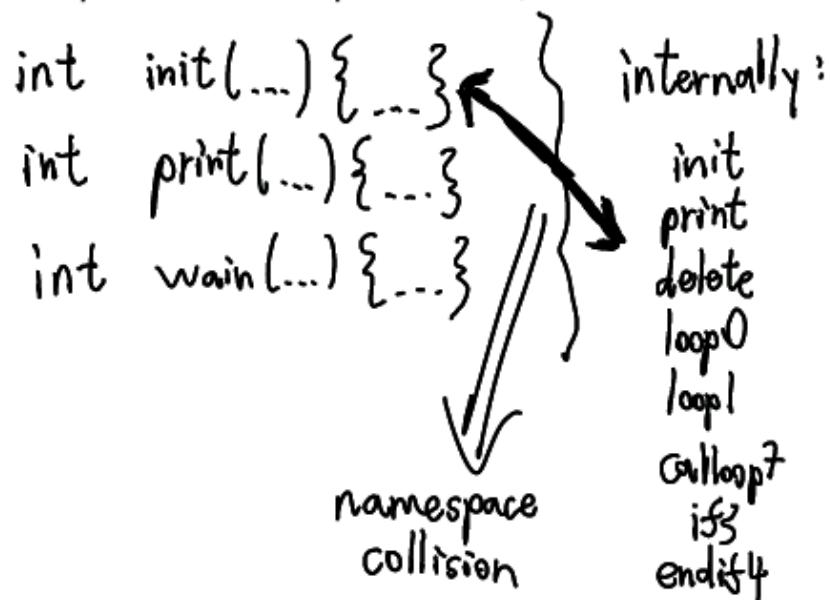

Verdict and MIPS outline:

f saves \$29

f: ---  
push(\$29)      jalr \$5  
push(\$31)      pop(\$31)  
lis \$5      pop(\$29)  
.word y  
5

## What's my name again?

If names of procedures map to labels, then...

Prepend "F" in front

$\Rightarrow F\langle \text{user proc name} \rangle$

e.g. Fprint

6

Finit

## Parameters

Recall what we did with the symbol table for each procedure.

```
int wain(int a, int b){int c=0; return a;}
```

Symbol Table and Stack:

a	int	0
b	int	-1
c	int	-2

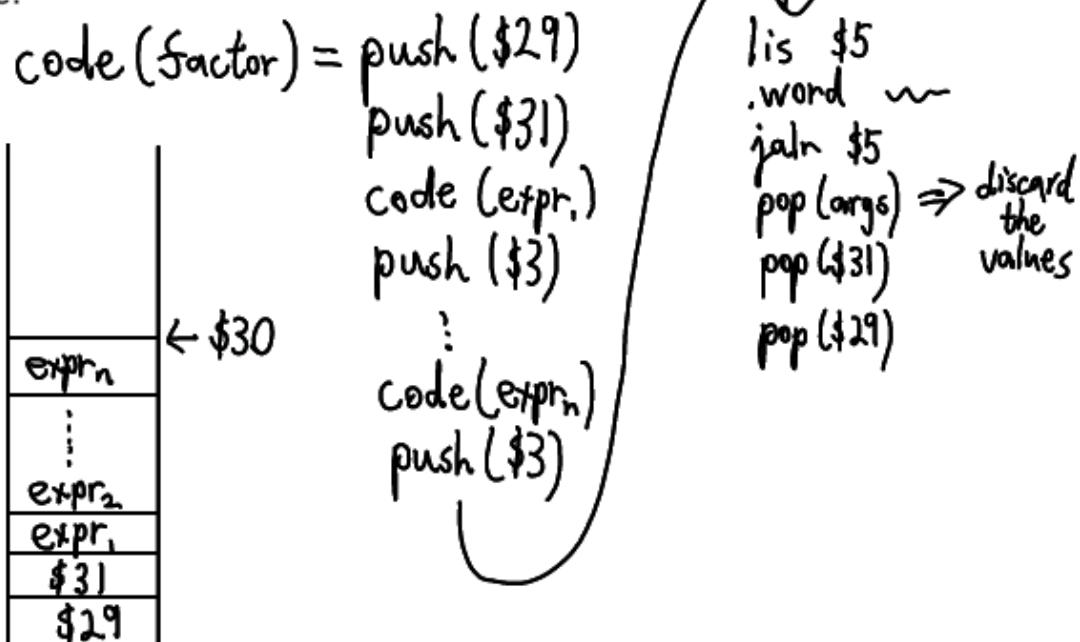

c	\$30
b	
a	\$29

## Parameter Ideas

We could use registers for parameters.

Or, we could be smart, since we could have a lot of parameters, as in:  
factor → ID(expr<sub>1</sub>, ..., expr<sub>n</sub>)

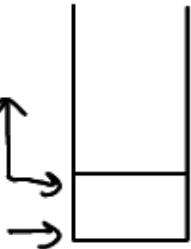

Code:

## Code for procedure

procedure → INT ID (params) { dcls stmts return expr; }

Code(procedure) = sub \$29, \$30, \$4  
+ push regs(\$1, \$2, \$5, \$6,  
\$29, \$31)

Problems?

why no  
code(params)

+ code(dcls) ← + code(stmts)  
+ code(expr)  
+ pop regs  
add \$30, \$29, \$4  
jr \$31

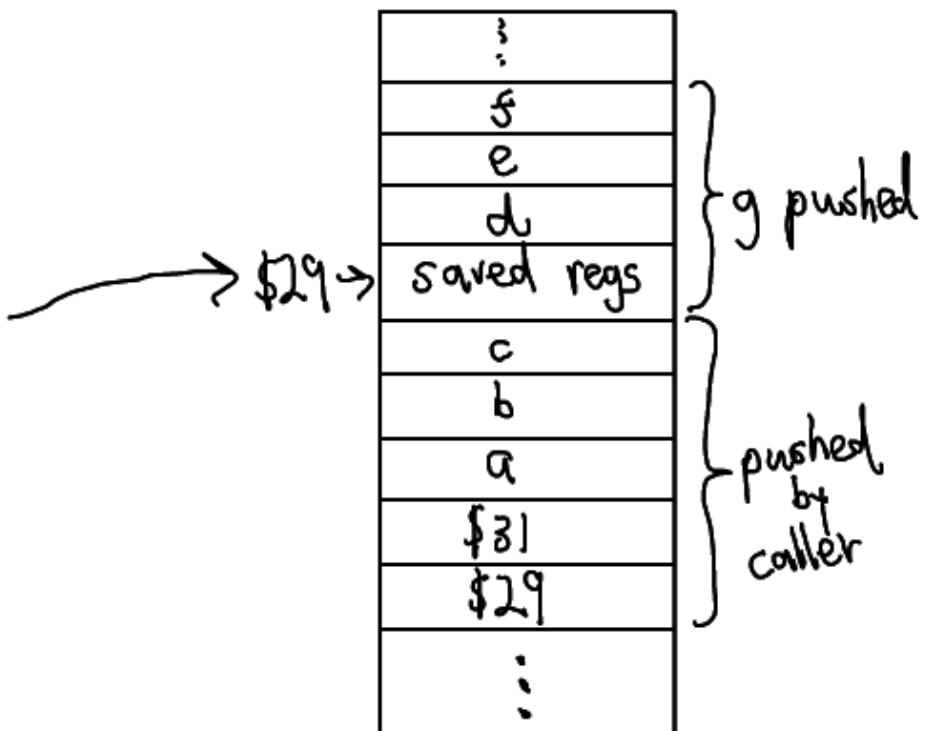

## Try an example

Suppose g (the callee) is:

```
int g(int a, int b, int c) {  
    int d=0;  
    int e=0;  
    int f=0;  
    ...  
}
```

Symbol Table and Picture:

a	int	0
b	int	-1
c	int	-2
d	int	-3
e	int	-4
f	int	-5

## Problems and Mathematical Fix

Parameters and local variables:

separated by my "saved registers"

Fix:  $\Rightarrow$  save registers after pushing local variables

Old symbol table values and new symbol table values:

Add (# of args) to offset

One last problem:

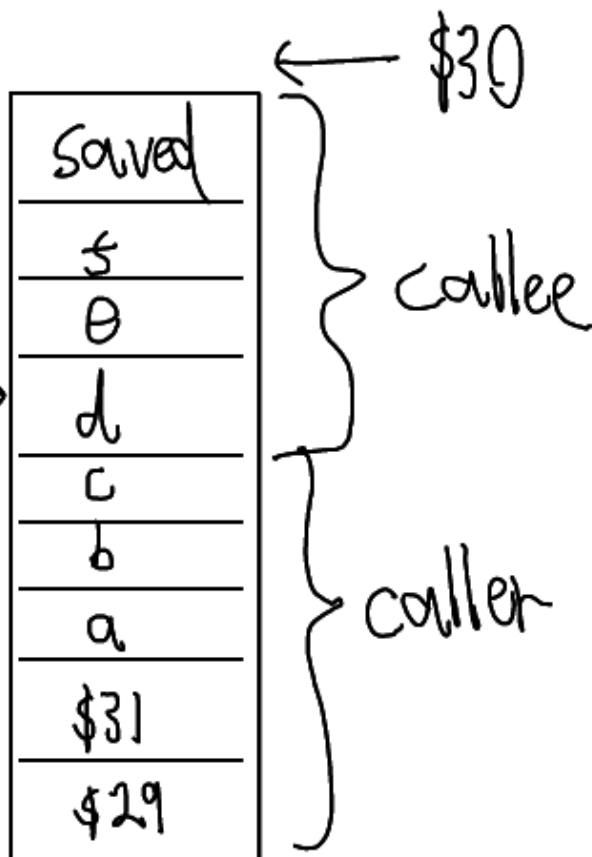

saved
s
e
d
c
b
a
\$31
\$29

## The big fix

Solution and picture

a	3
b	2
c	1
d	0
e	-1
f	-2

\$29 →  
first local variable

## Alternate fix?

Keep \$29 pointing at a  
→messy

Could also save all the registers in the caller, but...

`f() { g();  
g();  
g(); } }` } gets inefficient

## Optimization

CS444

Large and interesting topics: we will just skim.

Recall that we can have an infinite number of MIPS programs that are equivalent to a particular WLP4 program. What are the "good" MIPS programs that we would like to generate?

- ▶ ~~Maximizing~~ speed of instructions in actual code: hard  
increasing  $\Rightarrow$  some operations are faster:  
 $C++$  is slower than  $+C$ ;
- ▶ Reducing number of statements (stack usages, register allocation)

good approximation

Notice: minimal routine size is uncomputable.  
instead use heuristics.

## Optimization: Constant Folding

Consider an expression  $5+3$ .

What our compiler currently does:

```
lis $3  
.word 5  
sw $3, -4($30)  
sub $30, $30, $4
```

→

```
lis $3  
.word 3  
lw $5, 0($30)  
add $3, $5, $3  
add $30, $30, $4
```

What it could do:

```
lis $3  
.word 8
```

## Optimization: Constant Propagation

```
int x = 1;  
return x+x;
```

What our compiler currently does:

```
lis $3  
.word 1  
sw $3, -12($29)  
lw $3, -12($29)  
lw $3, -12($29)  
sw $3, -4($30)  
sub $30, $30, $4  
lw $3, -12($29)  
lw $5, 0($30)  
add $30, $30, $4  
add $3, $5, $3  
add $30, $29, $4  
jr $31
```

Or, we could use the fact that we know  $x = 1$  always and:

```
lis $3  
.word 1  
sw $3, -12($29)  
x=1 }  
lis $3  
.word 2  
jr $31
```

Further, if  $x$  is never used anywhere else:

```
lis $3  
.word 2
```

## Optimization: Common subexpression elimination

- ① Compute  $a+b$  into  $\$3$
- ② mult  $\$3, \$3$   
mflo  $\$3$

Imagine you had:

$$\underline{(a+b)} * \underline{(a+b)}$$

## Optimization: Dead-code elimination

What makes code dead?

↳ never executed  
↳ eg. test is always false  
⇒ logical implication

## Optimization: Register allocation

- ▶ Notice that many registers (i.e., \$14 through \$28) are not used by our compilation system.
- ▶ Notice that using registers would save instructions. Why?

no push/pop

- ▶ Suppose we could store 15 variables. Which ones would we store?

most used ones  
⇒ maintain priority

- ▶ & do you see a problem?

→ address - of ⇒ push out into RAM

## Optimization: Strength Reduction

- ▶ add is usually faster than mult (in the real world)
- ▶ however, in CS241, if we just count MIPS instructions, consider multiplying by 2

lis \$3  
.word 2  
lw \$5,0(\$30)  
add \$30, \$30, \$4  
mult \$3, \$2  
mflo \$3

vs.

add \$3, \$3, \$3

$\left[ \begin{matrix} \text{srl} & \$30, \$30, \$4 \\ \text{sub} & \$30, \$30, \$4 \end{matrix} \right]$

## Optimization: Inlining Procedures

```
int f(int x) { return x+x; }
int wain(int a, int b) { return f(a); }
```

↓

```
int wain(int a, int b) {
    return a+a;
```

Pros/Cons:

↳ if all calls  
to f are inlined,  
no need to generate  
the code for f at all

}  
if body of f is big  
and/or called many  
times, code expands.

## Optimization: Tail Recursion in Procedures

In WLP4, we must have exactly one return as the last statement in every function.

In other programming languages, you can say something like:

```
int fact(int n, int a) {  
    if (n==0) return a;  
    else return fact(n-1, n*a);  
}
```

$\text{fact}(3, 1)$   
 $\Rightarrow \text{fact}(2, 3)$   
 $\Rightarrow \text{fact}(1, 6)$   
 $\Rightarrow \text{fact}(0, 6) \Rightarrow 6$

Notice that the last thing the function does is returning a value: there is no additional work to be done. Thus, the frame can be reused!

## A few words about overloading

```
int f(int a) { ... } → Fi_f  
int f(int a, int* b) { ... } → Fip_f
```

Solved by name mangling:

F + <types of params> + — + <name>

Problems: C++

⇒ no standard on name mangling

⇒ had to link two pieces of code from different compilers

Solutions: extern ⇒ do not mangle my name!
