

# Lecture 3

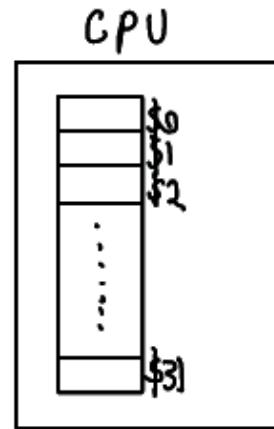

## Assembly language

Say something once, why say it again?

*CS 241: Foundations of Sequential Programs*  
Fall 2014

Troy Vasiga et al  
University of Waterloo

## Review

- ▶ MIPS has 18 instructions
- ▶ CPU contains 32 32-bit registers
- ▶ MIPS reference sheet for encoding of instructions
- ▶ `cs241.wordasm` to create binary files
- ▶ `mips.twooints` to start MIPS machine

           → reads \$1, \$2

## Special Registers

- ▶ \$0 ]— always 0
- ▶ \$29
- ▶ \$30
- ▶ \$31 ]— initially contains your return address,  
where to go to (PC value)  
when I am finished executing

## Assembly language

- ▶ encoding details can be automated
- ▶ 1-1 correspondence with machine language (almost)
- ▶ easier on the human eye
- ▶ uses different version of the assembler

## Example 0 revisited

- ▶ A1 level (machine language):

00000000 10100111 00011000 00100000  
00000011 11100000 00000000 00001000] → hex {word 0x.....}

- ▶ A2 level (assembly language):

add \$3, \$5, \$7  
jr \$31 ] — programming

- ▶ Which one would you rather read and debug?

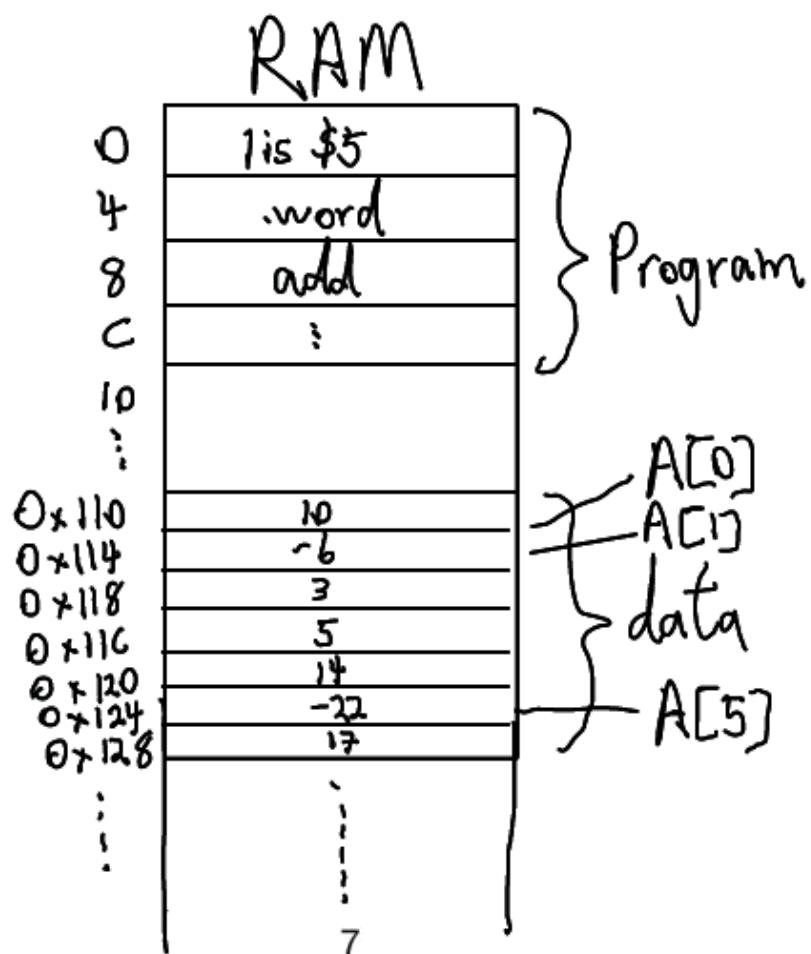

A3+A4 ⇒ write an assembler

## Examples 1,2,4

- ▶ Example 1 – adding two immediate values
- ▶ Example 2 – finding absolute values] if statement  
(conditional Evaluation)
- ▶ Example 4 – loop to sum integers from 1 to 13
  - =====
  - ↳ iterate / repeat

Turing Completeness

## Memory Revisited

## Example 3

- ▶ array access

## Example 5 – Output

There is no Input
